

# Autonomous Flight With the Ar Drone<sup>©</sup> drone

Maarten Inja and Maarten de Waard

UvA

January 26, 2011

## The Ar Drone<sup>©</sup>

The Ar Drone<sup>©</sup> is an over WiFi remote controlled quadrocopter that has several onboard sensors:

- One vertical camera, pointing downwards
- One horizontal camera, pointing forward
- Ultrasound altimeter, to measure the altitude
- 3 axis accelerometer (measures propellor acceleration)
- 2 axis gyrometer
- 1 yaw precision gyrometer

Furthermore, it has an onboard computer system running Linux.

## Our Goal

Summer-IMAV 2011 Indoor competition, some sub-tasks of the exploration challenge:

- Pick-up Object
- Exit Building
- Release Object

## Controlling The Drone

- Direct Control
  - Sending AT-Commands to ports
  - Listening on different ports to decode navigation data and video
- SDK, the Software Development Kit
  - A complete framework that takes care of decoding and encoding
  - Over complicated
  - Othermans work
- Extending C with Python
  - We are better at Python
  - Python seems like a better choice

## Finding The Object

To find the object the drone complete a search pattern

- Go to altitude X
- Rotate 360 degrees
- If the object has not been found, increase altitude X and repeat

## Recognizing The Object

- Convert video frame to HSV
- Discard pixels that do not match the color of the object
- Template match to find the middle of the object
- Calculate the distance by calculating the amount of pixels

## Pick Up The Object

- Centre the object in the middle of the screen
- Fly towards the object
- Hover in front of the object at a distance of 0.5 metre for some time to stabilize
- Fly above the object to pick it up
